# CSC-466 Lab 1: Assocp ciation Rules Mining

Vittorio Dinovi 4/17/18
Billy Gottentstrater

We used the strategy of *plotting* various minimum supports against the number of skyline frequent item sets discovered to observe a reasonable value of the minimum support. A similar approach was done with rules to find a reasonable minimum confidence. The rationale for selection was:

(1) For minimum support, choose a the value with the longest running *plateau* of item sets found before a large spike.

(2) For minimum confidence, choose a the maximum value along the longest *plateau* of rules found

The results for each dataset include the graph as justification for the choice of minimum support and minimum confidence.

** **Note** ** the number of skyline item sets identified in each *graph* is a slight overestimate due to a bug uncovered in the skyline extraction function. The supports and confidences derived from the graphs are still correct. Re-plotting these graphs would be very time-costly.

The correct skyline frequent itemsets and skyline rules are included in the logs

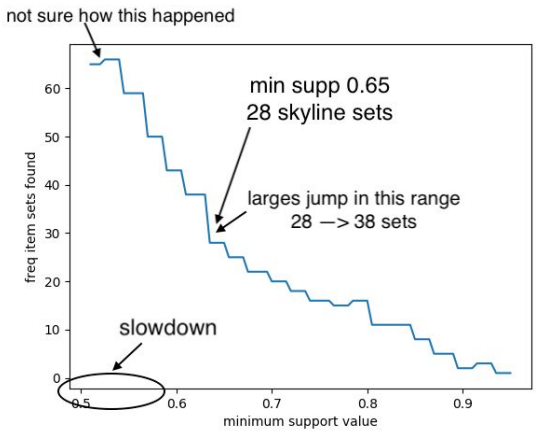
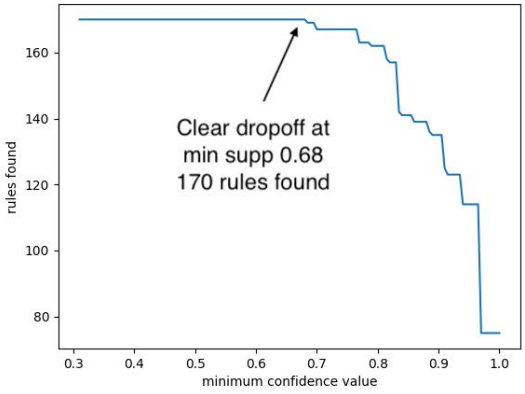
# Transcription Factors

These plots ended up being more difficult to decipher. The support experiences a transition from small gaps in the number of discovered item sets to increasingly larger gaps around 0.65. Thus, this seemed like a reasonable choice for the minimum support. The minimum confidence was much more obvious. After 0.68, the number of rules discovered stopped increasing





**Min. Support = 0.65** **Min. Confidence = 0.68**
